

Physics motivations for a GlueX cylindrical μ RWELL

3 μ RWELL modules with 4 mm drift gap each, from target center, cover polar angles between 14.42° and 165.579°

- ❖ Laying on the target vacuum chamber
- ❖ In the free space between target vacuum chamber and Start Counter
- GlueX: improve cascade processes resolution and detection efficiencies
- JEF: improve mass resolution of hypothetical BSM particles and allow search for BSM particles with displaced vertices
- KLF: improve kaon tracking and measurements of the vertex production

Target vacuum chamber & SC

- Target vacuum chamber cannot be changed
- To make room for uRWELL cablings, we will have to re-design how the SC is mounted

Geometry implementation - new SC configuration

Possible new mounting design

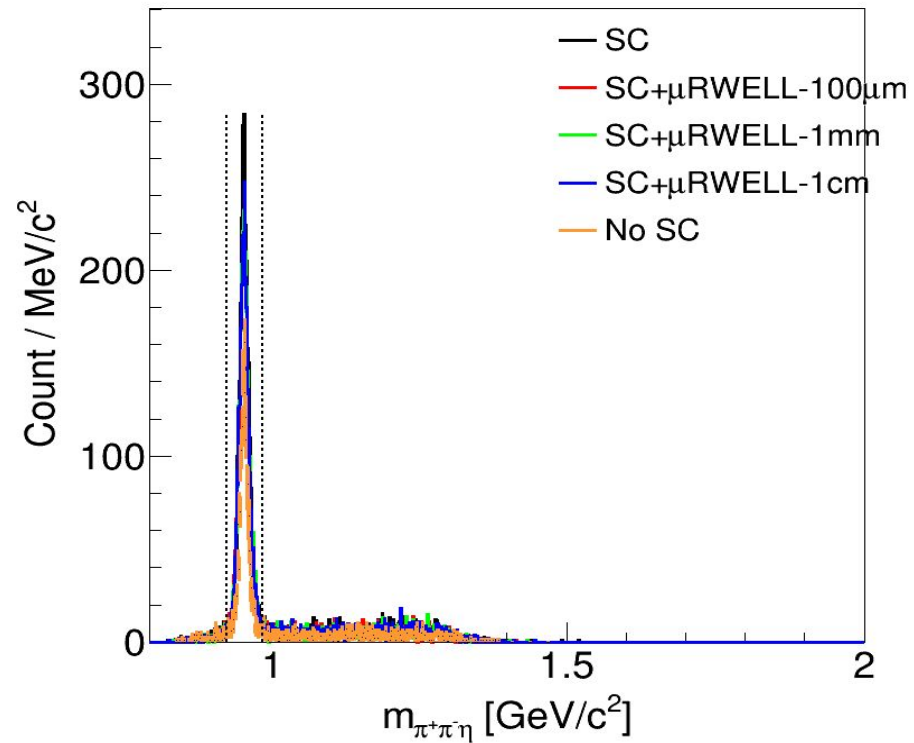

- Attach a ring to the target vacuum chamber
- Which is connected to SC via rods

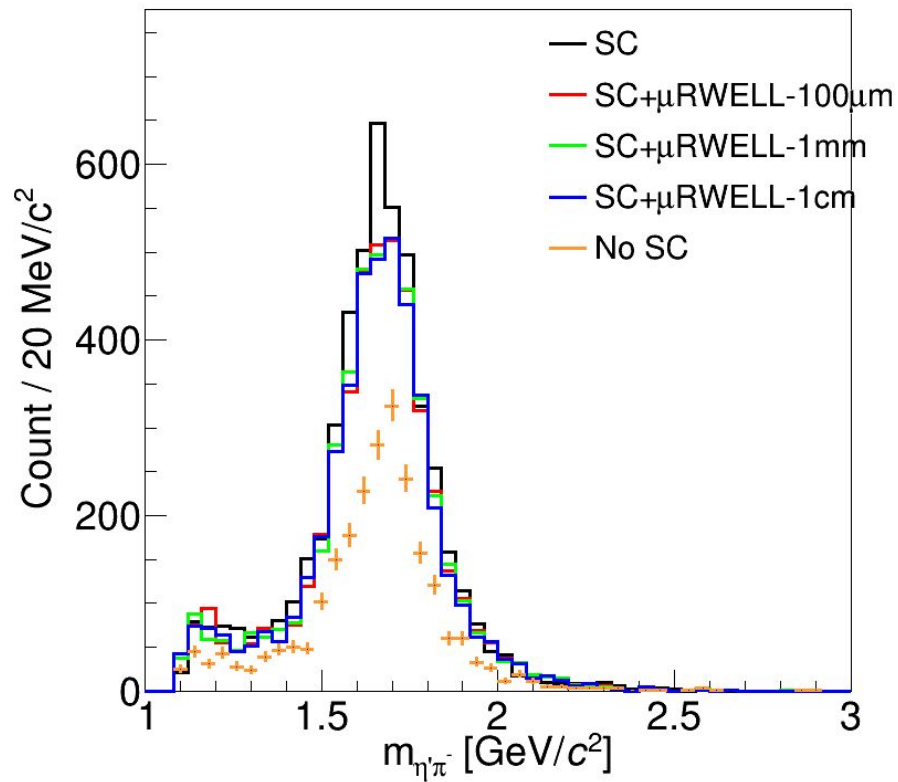

Gap allowing uRWELL cabling to come out

g p -> a_2(1700) pi^+ p

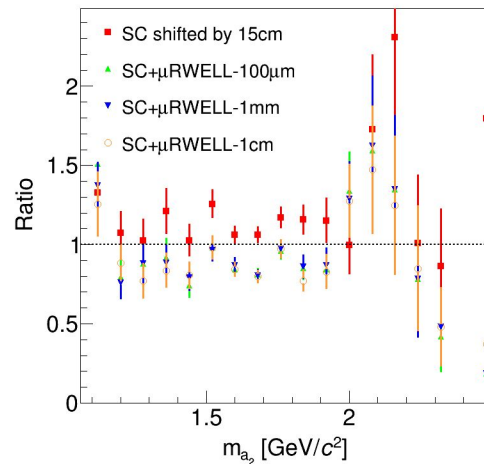

$a_2 \rightarrow \eta' \pi^-$, $\eta' \rightarrow \pi^+ \pi^-$ η , $\eta \rightarrow g g$

$a_2 \rightarrow \eta' \pi^-, \eta' \rightarrow \pi^+ \pi^- \eta, \eta \rightarrow g g$

Efficiency vs. t/m

- Shift appears to improve efficiency
- geantBEAM simulation underway to evaluate low energy photon background level

Conclusion

- SC has to be shifted downstream if new detector added in the free space between target vacuum chamber and SC
- Efficiency slightly improve if SC is moved downstream
- Background simulation is underway
- Between now and insert installation, a new mounting SC design could be tested
